

Title

scddata — Data Preparation for Synthetic Control Methods.

Syntax

```
scddata features [if] [in] , id(idvar) time(timevar) outcome(outcomevar) treatment(treatmentvar)  
dfname(string) [covadj(string) anticipation(#) cointegrated constant pypinocheck]
```

Description

scddata prepares the data to be used by **scest** or **scpi** to implement estimation and inference procedures for Synthetic Control (SC) methods. It allows the user to specify the outcome variable, the features of the treated unit to be matched, and covariate-adjustment feature by feature. The command follows the terminology proposed in [Cattaneo, Feng, and Titiunik \(2021\)](#). The command is a wrapper of the companion Python package. As such, the user needs to have a running version of Python with the package installed. A tutorial on how to install Python and link it to Stata can be found [here](#).

Companion [R](#) and [Python](#) packages are described in [Cattaneo, Feng, Palomba and Titiunik \(2022\)](#).

Companion commands are: **scest** for point estimation, **scpi** for inference procedures, and **scplot** for SC plots.

Related Stata, R, and Python packages useful for inference in SC designs are described in the following website:

<https://nppackages.github.io/scpi/>

For an introduction to synthetic control methods, see [Abadie \(2021\)](#) and references therein.

In case of unbalanced panel datasets, the preferred data structure should be a balanced panel with missing values. See [tsfill, full](#) for a useful command to create balanced structures.

Options

Variables

id(*idvar*) specifies the variable containing the identifier for each unit.

time(*timevar*) specifies the variable containing the time period of each observation.

outcome(*outcomevar*) specifies the outcome variable of interest. Note that *outcomevar* may not be among the *features* specified.

treatment(*treatmentvar*) specifies the treatment indicator.

Estimator

covadj(*string*) specifies the variables to be used for adjustment for each feature. If the user wants to specify the same set of covariates for all features, a string should be provided according to the following format: **covadj**("cov1, cov2"). If instead a different set of covariates per feature has to be specified, then the following format should be used **covadj**("cov1, cov2; cov1, cov3"). Note that in this latter case the number of sub-lists delimited by ";" must be equal to the number of *features*. Moreover, the order of the sub-lists matters, in the sense that the first sub-list is interpreted as the set of covariates used for adjustment for the first feature, and so on. Finally, the user can specify 'constant' and 'trend' as covariates even if they are not present in the loaded dataset, the former includes a constant, whilst the latter a linear deterministic trend.

anticipation(#) specifies the number of periods of potential anticipation effects. Default is **anticipation**(0).

cointegrated if specified indicates that there is a belief the features form a cointegrated system.

constant if specified includes a constant term across features.

Others

dfname(*string*) specifies the name of the Python object that is saved and that will be passed to **scest** or **scpi**.

pypinocheck) if specified avoids to check that the version of **scpi_pkg** in Python is the one required by **scddata** in Stata. When not specified performs the check and stores a macro called to avoid checking it multiple times.{p_end

Example: Germany Data

Setup

```
. use scpi_germany.dta
```

Prepare data

```
. scddata gdp, dfname("python_scddata") id(country) outcome(gdp) time(year) treatment(status)  
cointegrated
```

Stored results

`sccdata` stores the following in `e()`:

Scalars

`e(J)` number of donors
`e(KM)` total number of covariates used for adjustment

Macros

`e(features)` name of features
`e(outcomevar)` name of outcome variable
`e(constant)` logical indicating the presence of a common constant across features
`e(cointegrated_data)` logical indicating cointegration

Matrices

`e(A)` pre-treatment features of the treated unit
`e(B)` pre-treatment features of the control units
`e(C)` covariates used for adjustment
`e(P)` predictor matrix
